

Strategic Aid Allocation: A Data-Driven Approach to Maximize Impact

Parth Patel

4 min read · Just now

...

Introduction

Humanitarian organizations often face the challenge of strategically allocating limited resources to achieve maximum impact. With \$10 million raised, our goal was to identify the most vulnerable countries requiring aid and optimize fund allocation for poverty alleviation and community development. Using advanced data analytics, this project leverages clustering algorithms, exploratory data analysis (EDA), and predictive modeling to provide actionable insights.

This blog details the journey of solving the problem, from data preprocessing and EDA to hypothesis testing, modeling, and deployment,

alongside key insights and recommendations.

Problem Statement

A humanitarian NGO must strategically allocate \$10 million to maximize the impact of aid. The challenge is to:

1. Identify countries in dire need based on socio-economic and health indicators.
2. Group countries into clusters with similar needs to streamline resource allocation.
3. Provide actionable recommendations to improve outcomes in critical areas like health, education, and infrastructure.

Dataset Overview

The dataset used includes the following key features:

- **Country:** Name of the country.
- **Child Mortality:** Deaths of children under 5 years per 1000 live births.
- **Exports:** Exports as a percentage of GDP.
- **Health:** Health spending as a percentage of GDP.
- **Imports:** Imports as a percentage of GDP.
- **Income:** Net income per person.

- **Inflation:** Annual inflation rate.
- **Life Expectancy:** Average number of years a newborn is expected to live.
- **Fertility Rate:** Average number of children born per woman.
- **GDP per Capita:** GDP per person.

Step 1: Exploratory Data Analysis (EDA)

Univariate Analysis

Key Observations:

- Countries with high child mortality rates often have low income and life expectancy.
- A large disparity exists in GDP per capita among countries.

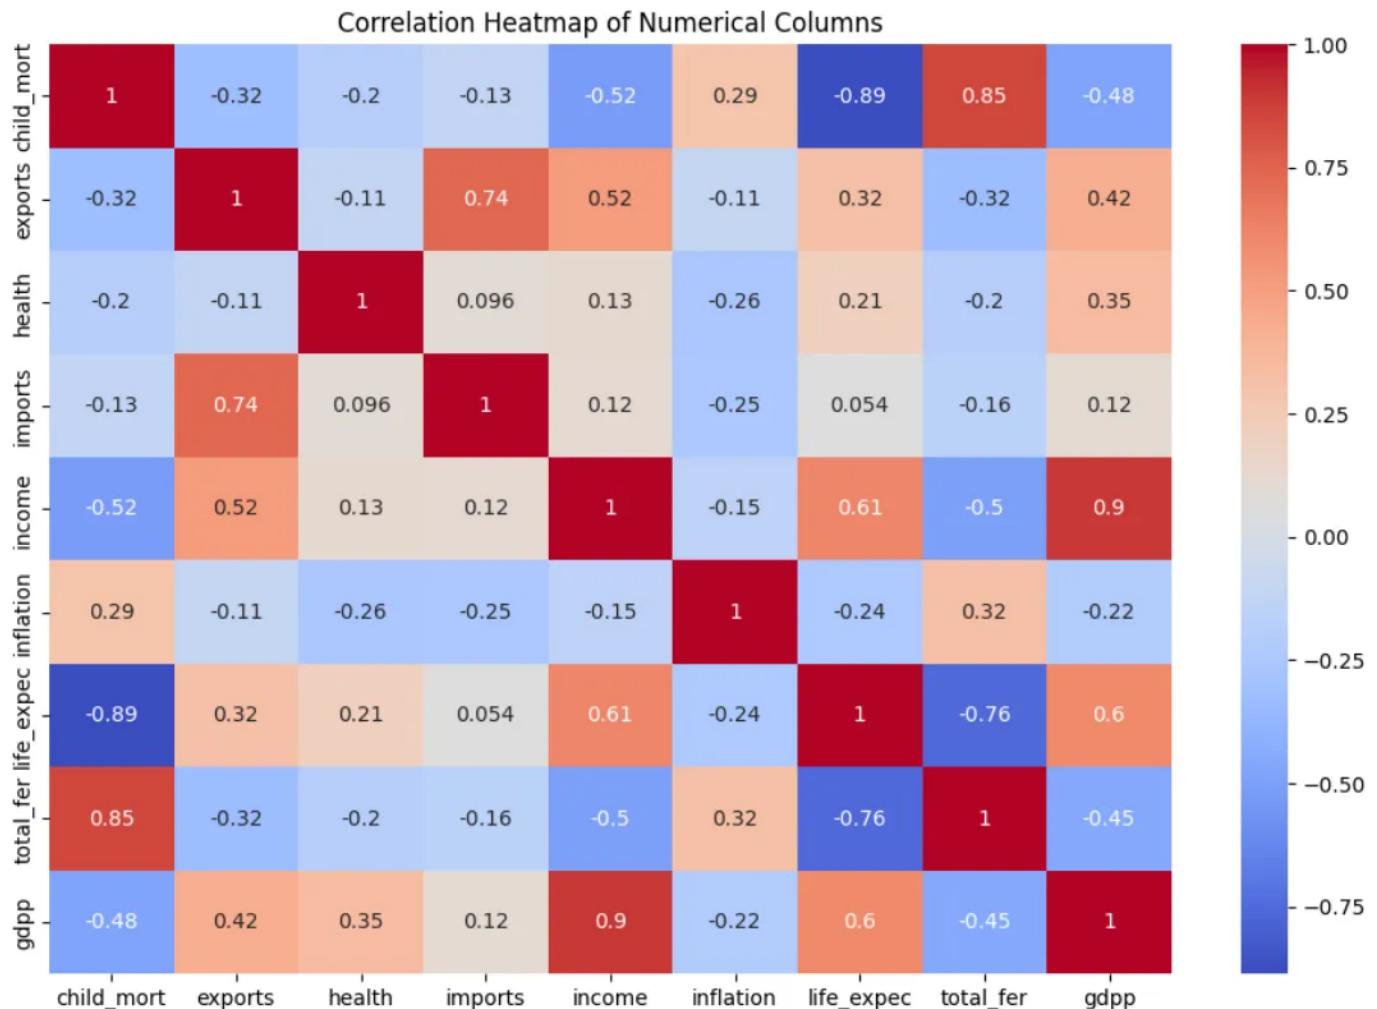

Insights:

- Child mortality rates ranged from 2.6 to 208 per 1000 live births.
- Health spending was low in countries with high child mortality.

Visualization:

- Distribution plots for GDP per capita, child mortality, and health spending revealed skewness. Log transformations were applied to

normalize the data.

Heatmap illustrating key performance indicators across various countries, highlighting areas requiring focused aid allocation

Bivariate Analysis

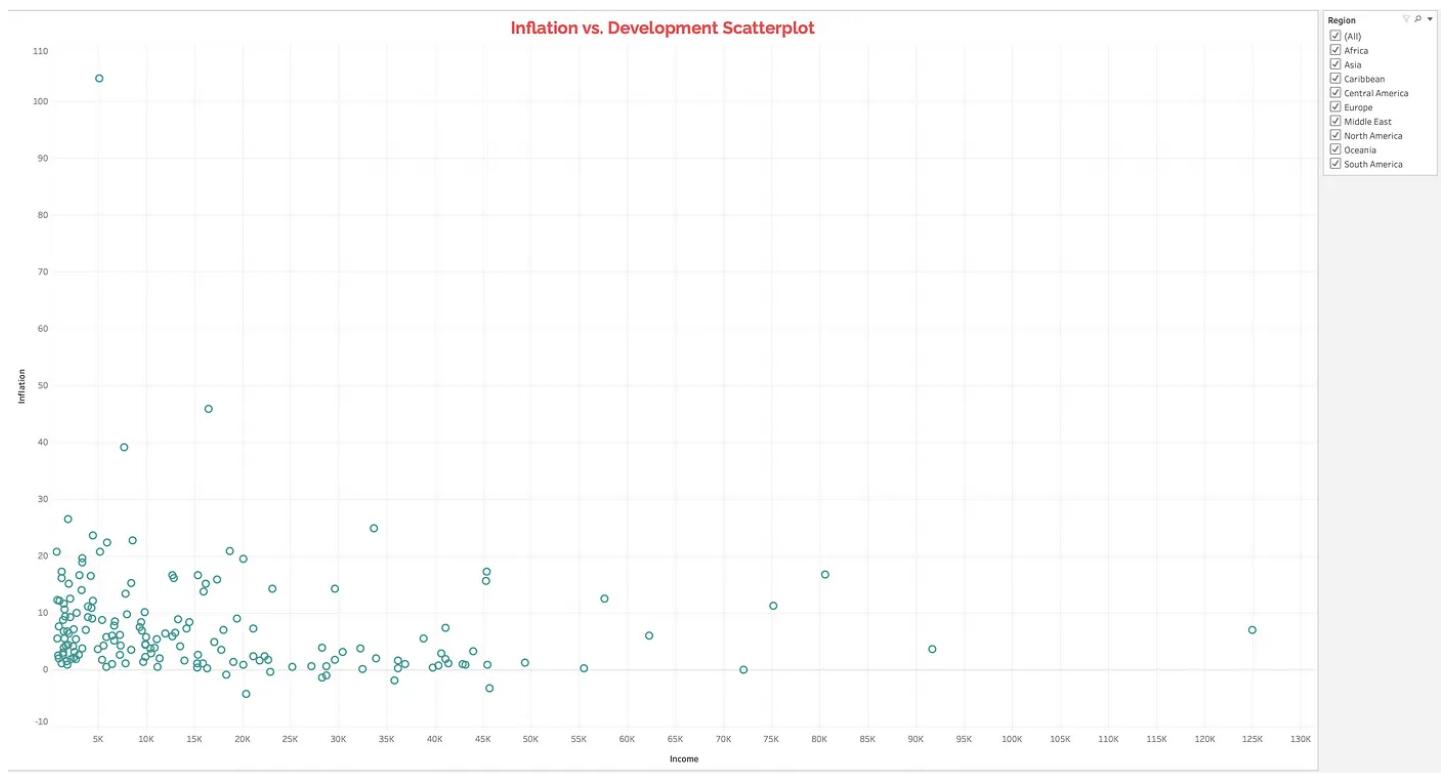

Key Relationships:

- A strong negative correlation ($\rho = -0.63$) exists between child mortality and income.

- Positive correlation ($\rho = 0.25$) between health spending and life expectancy.

Visualization:

- Correlation heatmaps highlighted critical relationships between features.

Scatterplot illustrating the relationship between inflation rates and development indicators across various countries.

Outlier Detection and Treatment

Techniques:

- Winsorization was applied to cap outliers in child mortality, exports, and imports.

Step 2: Hypothesis Testing

Hypothesis 1: Increased health spending improves life expectancy.

- T-test Results:
- t-statistic: -97.99
- p-value: 4.22×10^{-247}
- Conclusion: Reject the null hypothesis. Increased health spending significantly correlates with higher life expectancy.

Hypothesis 2: Higher income reduces child mortality.

- T-test Results:
- t-statistic: -13.68
- p-value: 4.27×10^{-34}
- Conclusion: Higher income is strongly associated with lower child mortality rates.

Step 3: Feature Engineering

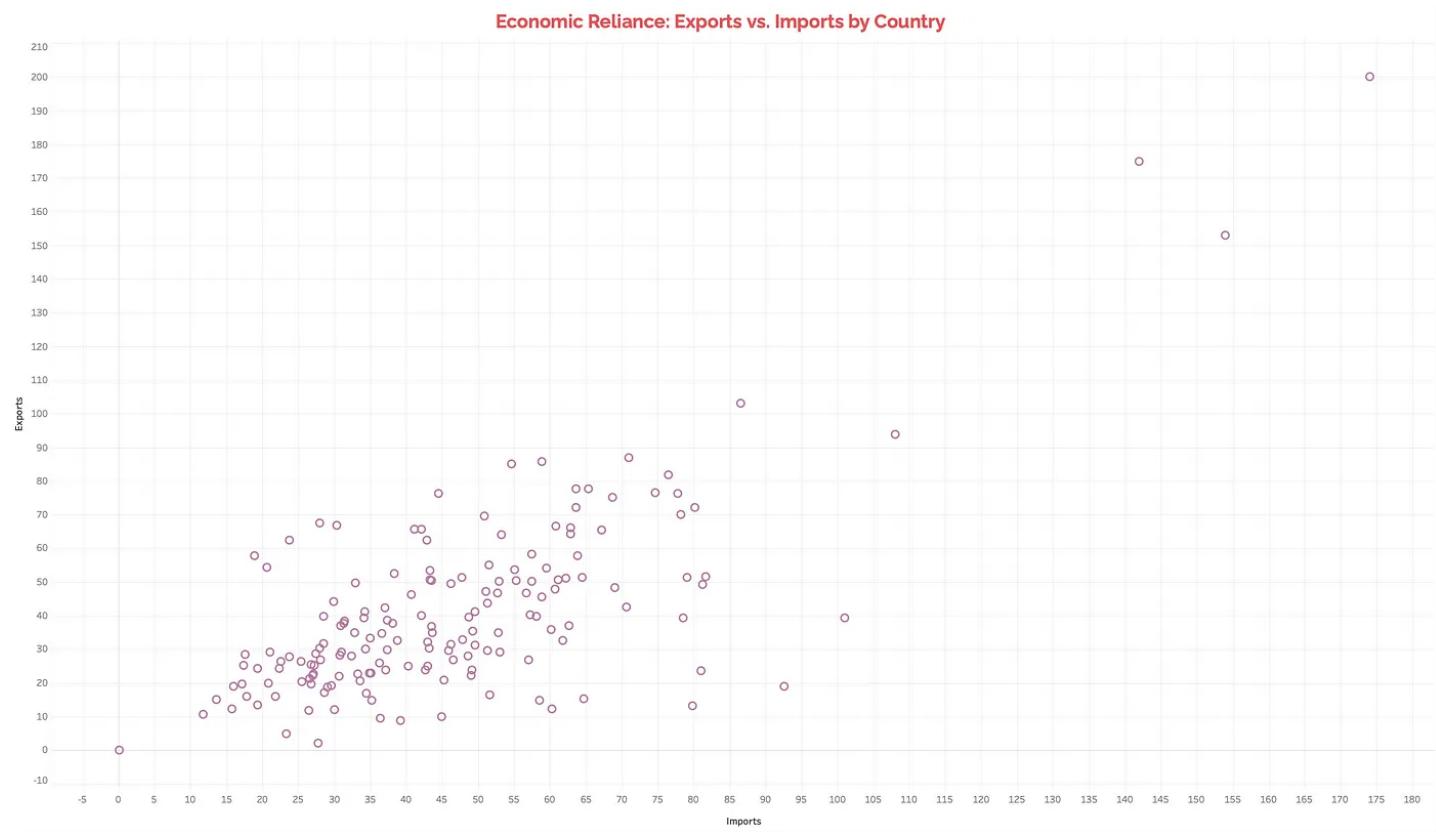

New Features Created:

- **Import-Export Ratio:** Exports/Imports to understand economic reliance.
- **Log GDP:** Applied log transformation to normalize GDP per capita.
- **Regional Encoding:** Grouped countries into regions (e.g., South Asia, Africa) for better clustering.

Scaling:

- StandardScaler was applied to normalize numerical features.

Step 4: Clustering and Modeling

Clustering Techniques

K-Means Clustering:

- Optimal number of clusters: 3 (determined using the Elbow Method).
- Clusters represented distinct socio-economic profiles.

Hierarchical Clustering:

- Visualized through dendograms.
- Confirmed 3-cluster structure.

DBSCAN:

- Identified noise points and outliers but showed less-defined clusters compared to K-Means.

PCA for Dimensionality Reduction:

- Reduced features to two principal components for visualization.

Cluster Insights

- **Cluster 0:** High child mortality, low income, and low GDP.
- **Cluster 1:** Moderate child mortality and income levels.

- **Cluster 2:** Low child mortality, high income, and high GDP.

Step 5: Deployment

Model Deployment

K-Means Model Pickle:

- Exported using Pickle for integration into dashboards.

Interactive Dashboard:

- Built with Python and hosted on Google Colab.
- Visualized country clusters, correlations, and key metrics.

Deployment Link: [Colab Notebook](#)

GitHub Repository: [GitHub Repo](#)

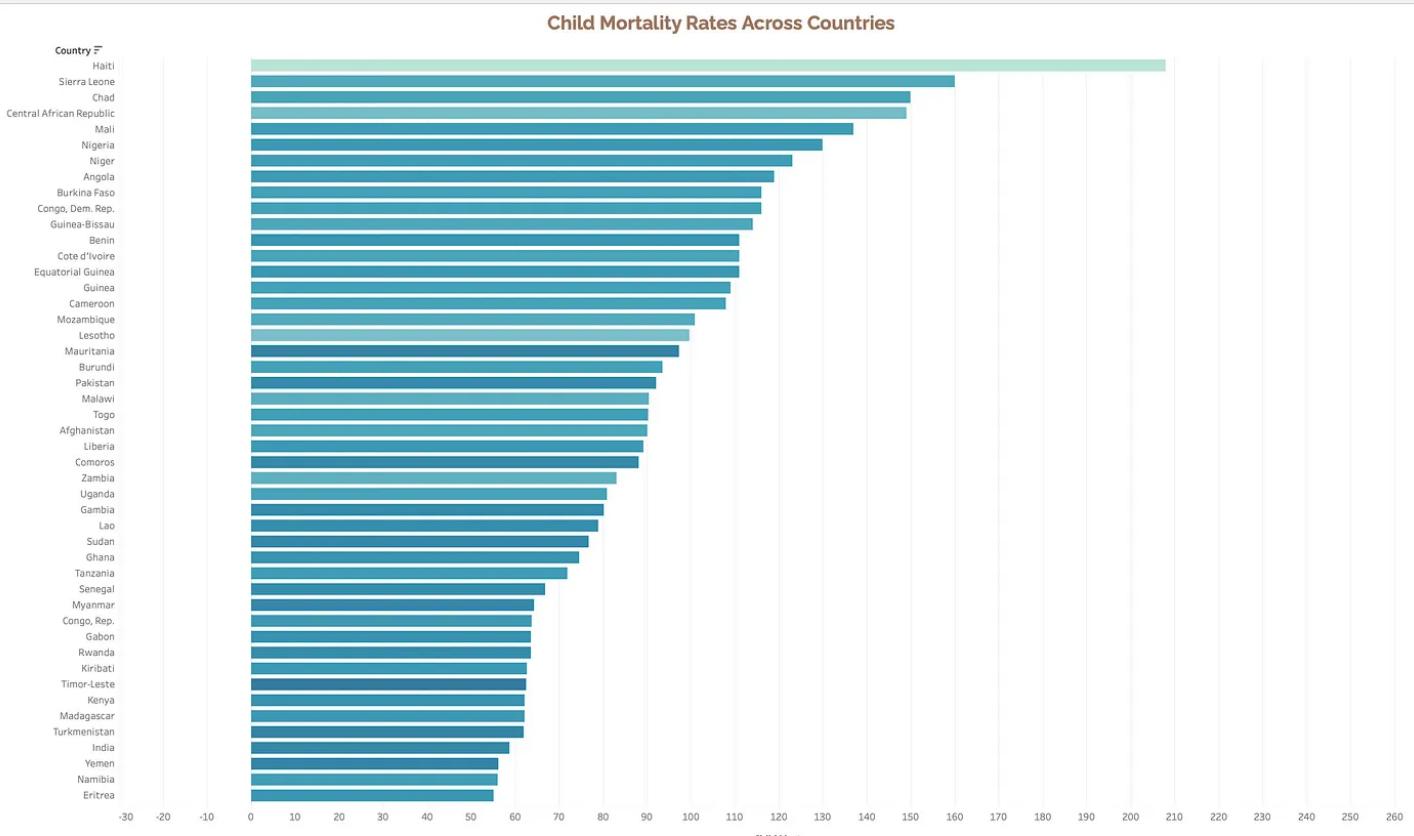

Tableau Dashboard: [Tableau Dashboard](#)

Key Insights and Recommendations

Invest in Healthcare:

- Fund immunization programs and enhance maternal healthcare to

reduce child mortality.

Strengthen Local Health Systems:

- Collaborate with local organizations to supply medical resources and train healthcare workers.

Address Economic Disparities:

Invest in education and vocational training to improve income levels and reduce poverty

Promote Food Security:

- Support sustainable agriculture and nutritional education to address malnutrition.

Long-Term Development Projects:

- Focus on clean water access, renewable energy, and education to address root causes of poverty.

Conclusion

This project demonstrates how data analytics can guide impactful decision-making in resource allocation. By clustering countries based on socio-economic and health metrics, we provided actionable recommendations to maximize aid impact. Future work can incorporate real-time data to refine insights and adapt strategies dynamically.

```

195     if (menuItems != null) {
196         handleMenuItemSelection(menuItem);
197     }
198 }
199
200 child: Dismissible(
201   key: Key.widget.clipId,
202   background: Container(
203     color: Colors.red,
204     alignment: Alignment.centerRight,
205     padding: EdgeInsets.only(right: 16.0),
206     child: From(
207       Icons.delete,
208       color: Colors.white,
209     ), // Icon
210   ),
211   direction: DismissDirection.endToStart,
212   onDismissed: (direction) {
213     clipModel.deleteClip(clipId: widget.clipId);
214   },
215   child: Container(
216     color: widget.selected
217       ? Theme.of(context).primaryColorLight
218       : null,
219     padding: EdgeInsets.fromLTRB(10, 0, 0, 0),
220     child: Column(
221       children: [
222         Row(mainAxisSize: MainAxisSize.min, children: [

```

I'll help you add a dismissible widget to make the clip swipeable with a delete action. First, let me check the current implementation of the clip widget.

Analyzed [clip.widget.dart](#) +19 -2 284 Open diff

I'll modify the clip widget to make it dismissible with a delete action. I'll wrap the main content in a `Dismissible` widget and add a delete icon that appears when swiping. Let me update the file:

1. Wrapped the main Container widget with a `Dismissible` widget
 2. Added a unique key using the `clipId`
 3. Configured the background to show a red container with a white delete icon
 4. Set the dismiss direction to `endToStart`: (right to left swipe)
 5. Added an `onDismissed` callback that calls the existing `deleteClip` method
- Now you can:
